(54) A construction for milking animals

(57) A construction for milking animals, such as
cows, comprises a milking box (14) and a milking robot
(41) having a robot head (67) which carries one or more
teat cups (71 - 74; 94). The milking box (14) includes at
least two adjacently arranged milking box compart-

ments (15, 16) and the milking robot (41) is set-up in
such a manner that in a first compartment the robot
head (67) can enter from the one side and in a second
compartment from another side.

EP 0 990 385 A2

Description

[0001] The invention relates to a construction for milking animals as described in the preamble of claim 1.

[0002] Such a construction is known.

[0003] It is an object of the invention to realize a fast and efficient manner of milking the animals.

[0004] According to the invention this is achieved in that at least two adjacently arranged milking box compartments and the milking robot is set-up in such a manner that the robot head can enter in a first compartment from one side and in a second compartment from another side. In a specific embodiment, the milking box comprises two compartments arranged beside each other, while the milking robot can enter the first compartment from a right-hand side and in the second compartment from a left-hand side. According to the invention, the construction is implemented in such a manner that, during milking of a first animal in one compartment, a second animal can enter the other compartment. Thus it is achieved that both animals can be milked one after the other with the aid of the same set of teat cups. The milking robot is consequently used in an optimum manner.

[0005] In an advantageous embodiment, between the two milking box compartments there is present a straight guide, along which the milking robot is movable. This provides a set-up of the milking robot, which is extremely suitable to allow pivoting of the robot head into both compartments.

[0006] According to the invention, the milking robot has a frame which is movable along the straight guide and is adjustable in height, and to which the robot head is pivotably attached in both milking box compartments. With the aid of a first operating cylinder, the frame can be moved along the straight guide. In an advantageous embodiment, the frame includes a first parallelogram structure which is operative in a substantial vertical plane and has a carrier, which is adjustable in height by a second operating cylinder, for the robot head. Further there may be present a second parallelogram structure which is operative in a substantial horizontal plane and by means of which the robot head is pivotably connected to the carrier. Because of the movability of the milking robot in the longitudinal direction passing between the two compartments, the adjustability in height of the robot head and the pivotability of the robot head in each of the adjacent milking box compartments, a milking robot set-up is obtained in which it becomes possible to move the robot head in an efficient manner to under the udder of the animal waiting in one of the compartments. The second parallelogram structure may include a third operating cylinder for rotating the robot head about an upwardly directed shaft relative to the frame. This rotational feature, in combination with the lateral pivotal feature of the robot head and the motion of the robot head in the longitudinal direction of the milking box compartments enables a positioning of

the robot head under the udder in such a manner that the teat cups can be connected in an efficient manner one after the other by an upward motion to the teats of the animal present in the relevant compartment. For pivoting the robot head in the two compartments, a fourth operating cylinder is present, which is connected to the upwardly movable portion of the milking robot, and more in particular to the said carrier. To ensure that, independently of the position of the legs of the animal in a milking box compartment, the robot head can be moved without problems to under the animal's udder, it is, in accordance with the invention, advantageous when the construction includes one or more sensors for determining the distance of the robot head to one or more legs of an animal present in a milking box compartment. The sensor/sensors for the determination of the distance of the robot head to one or more legs of an animal present in a milking box compartment is/are preferably provided on the robot head itself. The sensor is preferably constituted by a laser telemeter. This laser telemeter may be provided on a laser unit located on the robot head for determining the position of the teats of an animal present in a milking box compartment.

[0007] In order to effect successive cleaning of the teats and milking of the animals in an efficient manner, it is also advantageous to utilize the dual box, i.e. a milking box which comprises two adjacently arranged milking box compartments. The invention therefore also relates to a construction for automatically milking animals, such as cows, comprising a milking box and a milking robot having a robot head which acts as a carrier for one or more teat cups, the construction then being characterized in that it includes a cleaning member for cleaning the teats of the animals, which is disposed in such a manner that it can pivot to a milking box compartment on the one side and to a milking box compartment on the other side. By arranging both the milking robot proper and the cleaning member in such a manner that they are pivotal between the two milking box compartments, it becomes possible to pivot the cleaning member to under the udder of an animal in one compartment and, during subsequent cleaning of the teats, to pivot the milking robot arm carrying the teat cups to under an animal present in the other compartment or to keep it there, so that cleaning of an animal can basically be effected simultaneously with milking of another animal.

[0008] When an animal finally reaches the milking box, passing through the area, particularly through the shed and optionally through the pasture, the teats and/or the udder must be cleaned, before the animal is milked. Although several ways for cleaning the teats are known, the present invention provides a new manner of cleaning. To that end, the invention relates to a construction for automatically milking animals, such as cows, comprising a milking box with a milking robot and an area in which the animals can freely move about, the construction then being characterized in that it includes

a cleaning member for cleaning the teats of the animals, which member is capable of rotating about a shaft which extends in the longitudinal direction of the box.

[0009] For a better understanding of the invention and to show how the same may be carried into effect, reference will now be made, by way of example, to the accompanying drawings, in which:

Figure 1 shows a lay-out of a shed with a milking box, it being possible to pass through the shed and the milking box in one direction only;

Figure 2 shows a lay-out of a shed as shown in Figure 1 and a pasture contiguous thereto, it being possible to pass through the shed with the milking box and the pasture in one direction only;

Figure 3 shows a door which can open in one direction only, such as it is present in the shed, to ensure that the shed and the milking box can only be passed through in one direction;

Figure 4 shows a collar which, in addition to a cow identification system, is also provided with a radio system for encouraging the animal to pass through the shed and optionally the pasture on its way to the milking robot;

Figure 5 is a plan view of a milking box formed by two compartments, a milking robot being arranged such as to be pivotal between the two compartments;

Figure 6 is a side view of the milking robot in Figure 5;

Figure 7 is a rear view of a portion of the milking robot in Figure 5;

Figure 8 is a plan view of another embodiment of a milking box formed by two compartments, a milking robot and a cleaning member being arranged such as to be pivotal between the two compartments;

Figure 9 is a side view of a portion of the milking robot in Figure 8;

Figure 10 is a rear view of the milking robot as well as of the cleaning member arranged visibly in front thereof;

Figure 11 is a front view of the cleaning member in Figure 8;

Figure 12 is a longitudinal section through the cleaning elements of the cleaning member, and

Figure 13 is a cross-sectional view of that portion of the cleaning member that is shown in Figure 12.

[0010] Figure 1 shows a shed, particularly a loose housing 1, in which cows can move freely and in the longitudinal direction whereof a feeding area 2 is provided. Cubicles 3 are arranged on both sides of this feeding area 2 through substantially the overall length of the shed 1 along the inner side of the outer wall. The shed, which is split into two parts by the feeding area 2, is in the present embodiment divided in its totality into four areas 4, 5, 6 and 7. The animals present in the shed can reach these areas via doors or gates 8, 9, 10, 11 and 12

which open in one direction only. Figure 3 shows an embodiment of these doors. At one of the short sides of the shed there is an area 13, in which a dual milking box 14, i.e. a milking box formed by two compartments 15 and 16, is set-up. The compartments 15 and 16 of this milking box 14 can be entered through doors 17 and 18, whilst these compartments can be left through doors 19 and 20. The system of doors opening in only one direction defines the path and the direction in which the animals can walk through the shed and the milking box. Thus, the animals can proceed from the area 4 through the doors 9 to the area 5, from there through the doors 10 to the area 6, through the doors 11 to the area 7 and through the doors 12 to the area 13, respectively, where the milking box 14 is located, and from the area 13 through the doors 8 to the area 4 again. The animals can push the doors 8, 9, 10, 11 and 12 open in one direction. In addition, it is possible to open the doors under the control of a computer, to keep them open during a given period of time, or to close them; this will be described in greater detail hereinafter. In addition, the shed has doors 21 and 22 and, in the outer wall, doors 23 and 24, through which persons can reach the feeding area 2, it being prevented that at that moment animals might enter this feeding area 2 from the area 5 or from the area 13. Through the doors 23 and 21 or through the doors 24 and 22 fodder can be brought into the feeding area 2, optionally with the aid of a tractor. Gutters or troughs for fodder may then be provided on the partition between the feeding area 2 and the areas 4 - 7.

[0011] In order to realize a desired distribution of the total number of animals present in the shed over the areas 4 - 7, it should first be determined how many animals are present in each area at a given moment. This can be effected by providing each one of the doors 8 - 12, which open in one direction, with a counting device for counting the animals which move from one area to another through a relevant door. The counting devices may be connected to a computer, in which the number of animals in a given area can permanently be updated. When at a given instant too many animals are present in a given area in proportion to the number of animals in the other areas, then steps can be taken to effect that animals go from this one area to the next area. This can be achieved by ensuring that the computer keeps the relevant doors open for such a long period of time as necessary for a number of animals in the area in front of these doors to go to the next area through the doors. When the computer has ascertained that a given number of animals have moved from one area to another, as a result of which the overall number of animals in the first area has decreased to such an extent that the number corresponds to the normally desired number in such an area, the doors can again be closed under the control of the computer. Instead of, or optionally in addition to, the system of computer-controlled doors, use can alternatively be made of a radio system

25 having an aerial and a loudspeaker, which system is attached to animals. This radio system then operates in such a manner that, if too many animals are present in a given location, animals are encouraged by sound from the loudspeaker to go in one direction through the shed from one area to another. The radio system 25 can be attached to a collar 26 which the animals are wearing already, since such a collar is used as a carrier for the electronics of a cow identification system 27. Such a collar 26 is shown in Figure 4 and can consequently also function as a carrier for the electronics, including a loudspeaker and an aerial, relevant to the radio system 25. The aerial is preferably incorporated in its totality in the collar 26 itself.

[0012] Figure 2 again shows the shed 1, the difference being that now a pasture 28 is adjacent to the shed 1. In its longitudinal direction, the pasture 28 is provided for the major part with a railing, fence or a suchlike enclosure means 29 and in the transverse direction with a partition 30 which includes doors 31 and 32 which open in one direction. The pasture gives access to the shed 1 via doors 33 and 34 which open in one direction. From the area 4 the animals can pass through the doors 9 to the area 5 and from there via the doors 33 to the sub-pasture 35, via the doors 32 to the sub-pasture 36, via the doors 31 to the sub-pasture 37, via the doors 34 to the area 6, via the doors 11 to the area 7, via the doors 12 to the area 13, in which the milking box 14 is set-up, and from there via the doors 8 again to the area 4. Also in this situation, the animals can consequently pass through the shed and the pasture in only one direction.

[0013] The shed may be suitable for the accommodation of approximately sixty cows, which are milked three times a day. Between the consecutive milking runs, the animals have a period of rest in the shed and/or the pasture and a grazing period in the pasture of approximately seven hours, it being assumed that approximately one hour is needed for walking from the area or sub-pasture, in which an animal is present, to the area 13, in which the milking box 14 is positioned, for the period of time an animal has to wait before being allowed to enter the milking box 14, for cleaning and for the milking operation proper and for returning to the relevant area in the shed or to the relevant sub-pasture. The milking operation itself of the individual animals may take six to eight minutes.

[0014] The milking box 14, such as it is illustrated in Figure 5, is designed as a dual box, i.e. as a milking box which comprises two adjacently arranged milking box compartments 15 and 16. Access to these compartments is obtained via the doors 17 and 18, whilst the animals can be guided from the compartments through the doors 19 and 20. Each of the compartments has an automatic feeding implement, of which the feeder troughs 38 and 39 are shown in Figure 5. By means of the feeding implement, an animal present in a milking box compartment can be provided with an appropriate quantity of fodder during milking. Between the two com-

partments 15 and 16 there is an intermediate space 40, in which a computer-controlled milking robot 41 is positioned. The computer itself is not further shown. The two compartments 15 and 16 are of such a design that they are each other's mirror image. The two compartments are assembled from a rail system 42, in which the two longitudinal sides of the two compartments are provided with the doors 17 - 20 mentioned before. In addition, the compartments 15 and 16 have means 43 and 44, respectively, which are shown only very schematically in Figure 5, which have for their object to move and keep the animals to be milked to and in a somewhat strictly defined position in the milking box.

[0015] In the embodiment shown, the milking robot 41 includes a frame 47 which is movable along two rails 45 and 46 which form part of the rail system 42. This frame 47 is formed from cross-girders 50 and 51 which are interconnected by two beams 48 and 49 and at their two ends are provided with roller pairs 52 - 55, the frame 47 being movable with the aid of these roller pairs in the longitudinal direction over the rails 45 and 46 moving between the two compartments 15 and 16. The frame 47 can be moved over the rails 45 and 46 by means of a first operating cylinder 56 which has one side connected to the rearmost portion of the rail system 42 and its other side to the cross-girder 50 of the frame 47. In the midway point of the cross-girder 50 there is, rigidly connected to this cross-girder, a downwardly extending beam 57. This beam 57 is supported by a strut 58 arranged between the beam 57 and the cross-girder 51. A carrier 60 is connected to the lower end of the beam 57, via a first parallelogram structure 59 which is operative in a predominantly vertical plane. This carrier 60 includes a beam 61 which extends parallel to the beam 57, a rearwardly and slightly downwardly directed beam 62 and a strut 63 disposed between the beams 61 and 62. The carrier 60 can be moved up and down parallel to the beam 57 by means of a second operating cylinder 64 arranged between a lug 65 connected to the cross-girder 51 and the beam 62 of the carrier 60. Connected to the bottom side of the carrier 60, and more specifically to the bottom side of the beam 61 thereof, via a second parallelogram structure 66 which is operative in a predominantly horizontal plane, there is a robot head 67. Since the leading and trailing points of rotation of this second parallelogram structure are located on an imaginary horizontal axis in the transverse direction of the two compartments 15 and 16, a pivotal motion can be effected with the aid of this second parallelogram structure 66, by means of which the robot head 67 can be moved from one compartment to the other compartment and can then assume a substantially identical position in both compartments. By implementing one of the two connecting elements of the second parallelogram structure 66 as a (third) operating cylinder 68, the parallelogram formed by the parallelogram structure 66 can be slightly moved, whereby a rotation of the robot head 67 about an upwardly directed shaft relative to the

frame 47 of the milking robot 41 can be obtained. One of the rods of the second parallelogram structure 66 is provided with a lever arm 69 arranged at a square angle thereto. Arranged between the free end of this lever arm 69 and the leading end of the beam 62 of the carrier 60 there is a fourth operating cylinder 70, with the aid of which the pivotal motion of the robot head 67 can be realized. Because of the movability of the milking robot 41 in the longitudinal direction between the two compartments 15 and 16 with the aid of the first operating cylinder 56, the capability of moving up and down of the carrier 60 with the aid of the second operating cylinder 64, the pivotability of the robot head 67 from one compartment to the other with the aid of the fourth cylinder 70 and the rotatability of the robot head 67 about an upwardly directed shaft with the aid of the third operating cylinder 68, a virtually optimum combination of motional features is created, which renders it possible to move the robot head 67 in any desired position to under the udder of an animal to be milked. The robot head 67 acts as a carrier for four teat cups 71 - 74, whilst the carrier supports a laser unit 75 for determining the position of the teats of an animal present in a milking box compartment. In order to control the robot head 67 in such a manner that it can be moved to under the animal's udder without touching the animal's legs, the construction is provided with one or a plurality of sensors for determining the distance of the robot head 67 to one or more legs of an animal standing in a milking box compartment. Such a sensor, or such sensors, is/are preferably disposed on the robot head 67 itself. In the present embodiment, there is only one such sensor, which is designed as a laser telemeter 76 and is positioned on the said laser unit 75. Since the laser unit 75 for determining the position of the teats of an animal present in a milking box compartment is arranged such as to be capable of rotation, as is extensively described in the European patent application No. 0 360 354, the motor employed for rotating this laser unit 75 can also be used for rotating the laser telemeter 76, so that only one such laser telemeter is sufficient. With the aid of the signals supplied by the laser telemeter 76, the operating cylinders 56, 64, 68 and 70 can now be controlled in such a manner via the computer that the robot head 67 can be moved from a rest position between the compartments 15 and 16, i.e. from a rest position in the intermediate space 40, to under the animal's udder without touching the legs of the animal standing in a milking box compartment, whereafter, by means of the laser unit 75, the position of the animal's teats can accurately be determined and the robot head 67 can be moved such that the teat cups can be connected to the teats of the animal by an upward motion. When an animal in compartment 15 has been milked, an animal to be milked thereafter is given the opportunity to enter compartment 16. After the animal has entered compartment 16, the door 18 of this compartment can be closed and, as soon as the animal present in compartment 15 has been

milked, the robot head 67 can be pivoted from compartment 15 to under the udder of the animal standing in compartment 16 and the teat cups can then be connected to the teats of the animal then present in compartment 16. The other animal which has already been milked can then leave compartment 15 through the door 19 and the compartment is then empty, so that a further animal to be milked can enter compartment 15 through the door 17.

[0016] Although this is not of immediate importance for the present invention, it will be obvious that the teat cups, before they are connected to the teats of a subsequent animal, can be cleaned prior thereto. This might be done by pivoting the robot head 67 from one compartment to the intermediate space 40, by connecting the teat cups in this intermediate space to a cleaning unit, and, after the teat cups have been cleaned, by continued pivoting of the robot head 67 to the other compartment.

[0017] In Figures 8 - 13 a second embodiment of a milking box with two compartments is shown, wherein besides a milking robot there is provided a cleaning member for the teats of an animal to be milked. Therefore, between the compartments 15 and 16, in the intermediate space 40, there is arranged in the rest position besides the milking robot 41 a cleaning member 77. In the embodiment shown, the milking robot 41 includes a frame 78 which is movable over two rails 45 and 46 which form part of the rail system 42 of the two compartments. This frame 78 is formed by cross-beams 81 and 82 which are interconnected by beams 79 and 80 and at their two ends are fitted with pairs of rollers 83 - 86. Using these roller pairs, the frame 78 can be moved in the longitudinal direction, passing between the two milking box compartments 15 and 16, over the rails 45 and 46. This motion can, for example, be realized with the aid of an operating cylinder, which has one side connected to the leading portion of the rail system 42 and its other end to a cross-beam 81 of the frame 78. This cylinder is, however, not shown in the drawings. In the midway point of the lower cross-beam 81, downwardly extending beams 87 are present which are rigidly connected to this cross-beam. Connected to the lower end of the beams 87 there are carriers 89 with the aid of a parallelogram structure 88 which operates in a predominantly vertical plane. The carriers 89 can be moved up and down parallel to the beams 87 by means of an operating cylinder 90 arranged between lugs 91 connected to the upper cross-beam 82 and lugs 92 present on a beam between the carriers 89. At the lower side of the beams 89 there is a robot arm structure 93 with teat cups 94 and a sensor 95 for determining the position of the teats of an animal present in one of the compartments relative to the end of the robot arm structure 93, as there the teat cups 94 are located. The end of the robot arm structure 93 with the teat cups 94 is movable in a horizontal plane in the manner described hereinafter, whereas the robot arm structure 93 is movable in

the vertical direction by means of the cylinder 90. The robot arm structure 93 includes a parallelogram structure 96 which is pivotably connected to the carriers 89. One of the arms of this parallelogram structure includes an operating cylinder. As a result of the movement of the frame 78 over the rails 45 and 46, the pivotal motion to be performed with the aid of the parallelogram structure 96 and the rotational capability of the end of the robot arm structure 93 with the aid of the operating cylinder associated with the parallelogram structure 96, the teat cups 94 can be moved in any position to under the udder of an animal present in a compartment. The milking robot 41 is of such a design that the frame 78 is movable over the leading portion of the rails 45 and 46, whilst furthermore the parallelogram structure 96 is directed rearwardly, so that the end of the robot arm structure can be pivoted through between a front leg and a hind leg and can thereafter be moved to under the udder of the animal, more in particular in a position determined with the aid of the sensor 95.

[0018] As has already been mentioned in the foregoing, not only the milking robot 41 but also the cleaning member 77 is set-up in the intermediate space 40. In the embodiment shown, the cleaning member 77 includes a frame 97 which is movable over the rails 45 and 46. This frame 97 is formed from cross-beams 98 and 99 which are interconnected by beams 100 and 101 and at their two ends are provided with pairs of rollers 102 - 105. By means of these pairs of rollers, the frame 97 can be moved in the longitudinal direction through between the two milk box compartments 15 and 16 over the rails 45 and 46. This motion can, for example, be realized with the aid of an operating cylinder, which has one side connected to the rearmost portion of the rail system 42 and the other side to a cross-beam 98 of the frame 97. This cylinder is, however, not shown in the drawings. In the midway point of the lower cross-beam 99, downwardly extending beams 106 are present which are rigidly connected to this cross-beam. Connected to the lower end of the beams 106, with the aid of a parallelogram structure 107 which is operative in a predominantly vertical plane, there are carriers 108. The carriers 108 can be moved up and down parallel to the beams 106 with the aid of an operating cylinder 109, which is disposed between lugs 110 connected to the upper cross-beam 98 and lugs 111 connected to a beam between the carriers 108. Attached to the bottom side of the carriers 108 there is a double parallelogram structure which is formed by a first parallelogram structure 112 and a second parallelogram structure 113. A carrier 114 (see Figure 12), on which the component parts of a cleaning element 115 are disposed, is present at the end of the second parallelogram structure 113. By means of the second parallelogram structure 113, the cleaning element 115 can be pivoted from the intermediate space 40 to under the udder of an animal located in one of the compartments 15 or 16. By means of the first parallelogram structure 112, the second parallelo-

gram structure 113 and in conjunction therewith the cleaning element 115 can be moved to and fro in a direction transversely to the longitudinal direction of a compartment. This motion renders it possible to reciprocate the cleaning member under the udder and thereby to increase the cleaning effect.

[0019] The cleaning meter 115 comprises a container 116 which extends in the longitudinal direction of a compartment and a rod-like element 118 which is bearing-supported in the side walls of the container, and which is drivable by means of a motor 117 and is provided with textile discs 119. The rod-like element 118 with the textile discs 119 is rotatable by means of the motor 117 relative to the longitudinal direction of a milking box compartment. The textile discs 119 can rotate in two directions and during this rotary motion can be moved under the udder of an animal. The container 116 does not only function as a carrier for the rotatable textile discs 119, but also as a water receptacle and is provided at its bottom side with a plurality of apertures 120 which are arranged in a row. A water supply line 121 is located at the bottom side of the water receptacle. Through this supply line, water can be sprayed into the water receptacle 116, in order to clean the teats of an animal.

[0020] The present invention is not limited to the embodiments described in the foregoing, but also relates to all kinds of modifications thereof, insofar they are within the protective scope of the following claims. Alternatively more than two milking box compartments may be used. These compartments can, for example, be arranged in two rows.

Claims

1. A construction for milking animals, such as cows, comprising a milking box (14) and a milking robot (41) having a robot head (67) which carries one or more teat cups (71 - 74; 94), characterized in that the milking box (14) includes at least two adjacently arranged milking box compartments (15, 16) and the milking robot (41) is set-up in such a manner that in a first compartment the robot head (67) can enter from the one side and in a second compartment from another side.
2. A construction as claimed in claim 1, characterized in that the milking box (14) comprises two compartments (15, 16) arranged beside each other, whereas the milking robot (41) can enter the first compartment from a right-hand side and in the second compartment from a left-hand side.
3. A construction as claimed in claim 1 or 2, characterized in that the construction is arranged such that, during milking of an animal in one compartment, another animal can enter the other compartment, and that both animals can be milked one after the

other by means of the same set of teat cups (71 - 74; 94).

4. A construction as claimed in any one of the preceding claims, characterized in that between two milking box compartments (15, 16) rails (45, 46) are provided, along which the milking robot (41) can be moved.
5. A construction as claimed in claim 4, characterized in that the milking robot (41) includes a frame (47, 78) which is movable along the rails (45, 46) and is adjustable in height, and to which the robot head (67) is attached capably of pivoting in both milking box compartments (15, 16).
6. A construction as claimed in claim 5, characterized in that there is present an operating cylinder (56) for moving the frame (47, 78) along the rails (45, 46).
7. A construction as claimed in claim 5 or 6, characterized in that the frame (47, 48) includes a parallelogram structure (59, 88) which is operative in a predominantly vertical plane and includes a robot head carrier (60, 89) which is adjustable in height by means of an operating cylinder (64, 90).
8. A construction as claimed in claim 7, characterized in that there is present a further parallelogram structure (66, 96) which is operative in a predominantly horizontal plane and with the aid of which the robot head (67) is connected to the carrier (60, 89) such as to be pivotal in both milking box compartments (15, 16).
9. A construction as claimed in any one of claims 5 to 8, characterized in that the further parallelogram structure (66, 96) includes an operating cylinder (68) for rotating the robot head (67) about an upwardly directed shaft relative to the frame (47, 78).
10. A construction as claimed in any one of claims 5 to 9, characterized in that there is present a fourth operating cylinder (70) connected to the frame (47, 78) for pivoting the robot head (67) in the two milking box compartments (15, 16).
11. A construction as claimed in any one of the preceding claims, characterized in that it is provided with one or a plurality of sensors for determining the distance between the robot head (67) and one or more legs of an animal present in a milking box compartment (15, 16).
12. A construction as claimed in any one of the preceding claims, characterized in that the milking robot (41) includes a robot head (67) carrying four teat

cups (71 - 74; 94), the robot head (67) being arranged pivotably in such a manner that first an animal standing to the left thereof can be milked and thereafter an animal standing to the right side thereof.

13. A construction as claimed in any one of the preceding claims, characterized in that the construction includes a cleaning member (77) for cleaning the teats of the animals, the cleaning member (77) being arranged capably of rotation about a shaft which extends in the longitudinal direction of the milking box.
14. A construction as claimed in any one of the preceding claims, characterized in that the construction includes a cleaning member (77) for cleaning the teats of the animals, which member (77) is pivotably disposed between a milking box compartment provided to the left thereof and a milking box compartment provided to the right thereof.
15. A construction as claimed in claim 13 or 14, characterized in that the cleaning member (77) includes a rod-like element (118) with textile discs (119).
16. A construction as claimed in any one of claims 13 to 15, characterized in that the cleaning member (77) is arranged such that it is rotatable relative to the longitudinal direction of a milking box compartment.
17. A construction as claimed in any one of claims 13 to 16, characterized in that the cleaning member (77) can be moved into two opposite directions during cleaning.
18. A construction as claimed in any one of claims 13 to 17, characterized in that the cleaning member (77) includes a water receptacle (116).
19. A construction as claimed in any one of claims 13 to 18, characterized in that a water supply line (121) is provided under the water receptacle (116).
20. A construction for milking animals, such as cows, including a milking box (14) and a milking robot (41) having a robot head (67) which acts as a carrier for one or a plurality of teat cups (71 - 74; 94), characterized in that the construction is provided with one or a plurality of sensors (76) for determining the distance between the robot head (67) and one or more legs of an animal present in a milking box compartment (15, 16).
21. A construction as claimed in claim 20, characterized in that the sensor/sensors (76) for determining the distance between the robot head (67) and one or more legs of an animal present in the milking box

is/are disposed on the robot head (67).

22. A construction as claimed in claim 21, characterized in that a sensor (76) is constituted by a laser telemeter.

5

23. A construction as claimed in claim 22, characterized in that the laser telemeter (76) is accommodated on a laser unit (75) which is positioned on the robot head (67) for determining the position of the teats of an animal present in a milking box compartment (15, 16).
